#### Abstract

The results of ab initio correlated molecular orbital theory electronic structure calculations for low-lying electronic states are presented for UH and $\mathrm{UH}^{-}$and compared to photoelectron spectroscopy measurements. The calculations were performed at the $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ and multireference CASPT2 including spin-orbit effects by the state interacting approach levels. The ground states of UH and $\mathrm{UH}^{-}$are predicted to be ${ }^{4} \mathrm{I}_{9 / 2}$ and ${ }^{5} \Lambda_{6}$, respectively. The spectroscopic parameters $T_{e}, r_{e}, \omega_{e}, \omega_{\mathrm{e}} x_{\mathrm{e}}$, and $B_{\mathrm{e}}$ were obtained, and potential energy curves were calculated for the low energy $\Omega$ states of UH. The calculated adiabatic electron affinity is 0.468 eV in excellent agreement with an experimental value of $0.462 \pm 0.013 \mathrm{eV}$. The lowest vertical detachment energy was predicted to be 0.506 eV for the ground state, and the adiabatic ionization energy (IE) is predicted to be 6.116 eV . The bond dissociation energy (BDE) and heat of formation values of UH were obtained using the IE calculated at the Feller-Peterson-Dixon level. For $\mathrm{UH}, \mathrm{UH}^{-}$, and $\mathrm{UH}^{+}$, the BDEs were predicted to be $225.5,197.9$, and $235.5 \mathrm{~kJ} / \mathrm{mol}$, respectively. The BDE for UH is predicted to be $\sim 20 \%$ lower in energy than that for ThH . The analysis of the natural bond orbitals shows a significant $\mathrm{U}^{+} \mathrm{H}^{-}$ionic component in the bond of UH.

## - INTRODUCTION

Actinides and actinide-containing species are of special interest due to their unique chemical properties as well as their vital role in the field of nuclear energy. ${ }^{1,2}$ Because most actinides are radioactive, expensive to produce, and difficult to handle, experimental studies alone present a challenge to understanding the basic properties of molecules containing actinides. This is exacerbated by the potential for many low-lying electronic states due to the presence of partially occupied 5f and/or 6 d orbitals. Thus, a combination of experimental and theoretical approaches has become a useful approach for the study of the chemistry of heavy-element compounds. The uranium atom, one of the most studied actinides, has a $[\mathrm{Rn}] 5 f^{3} 6 \mathrm{~d}^{1} 7 \mathrm{~s}^{2}$ electronic configuration with a ${ }^{5} \mathrm{~K}_{\mathrm{u}}$ excited state, only $620 \mathrm{~cm}^{-1}$ above the ${ }^{5} \mathrm{~L}_{\mathrm{u}}$ ground state; there are around 30 states below $\sim 2.0 \mathrm{eV}$ in energy for $\mathrm{U}^{3}$ The chemistry of uranium is heavily dependent on its oxidation states with +4 and +6 being the most prevalent in natural compounds. ${ }^{4}$ The potential presence of electrons in both the 5 f and 6 d valence orbitals plays a significant role in determining the nature of the bonding and reactivity of $U$. The potential for the existence of many low-lying excited states in uranium compounds with low oxidation states can require the use of multireference methods including relativistic corrections to identify their ground states and to match available spectroscopic values. So far, Tang et al. ${ }^{5}$ have used slow-electron velocity-map imaging to obtain a value
of 0.31497(9) for the electron affinity (EA) of U. Likewise, Bowen, Peterson, and co-workers ${ }^{6}$ measured a value of $0.309 \pm$ 0.025 eV for the $\mathrm{EA}(\mathrm{U})$ using negative ion photoelectron spectroscopy, in agreement with the above result. Based on composite coupled cluster theory with single and double excitations with perturbative triples ( $\operatorname{CCSD}(\mathrm{T})$ ) with allelectron four-component spin-orbit coupling, they calculated the EA of U to be 0.232 eV , corresponding to detachment from a $6 d$ orbital on the $U$.
Several computational studies have been reported for uranium-containing diatomic molecules. ${ }^{7-18}$ The electronic structure of uranium monohydride (UH) resembles those of UF and UCl , which can be considered ionic $\mathrm{U}^{+} \mathrm{X}^{-}$; the uranium cation is perturbed by a closed-shell anion ligand. Bross and Peterson ${ }^{7}$ obtained a ${ }^{4} \mathrm{I}_{9 / 2}\left(\mathrm{U}^{+}\left(5 f^{3} 7 \mathrm{~s}^{2}\right)\right.$ ground state for UF and UCl from high-level correlated molecular orbital theory calculations, in agreement with previous calculations on UF by Antonov and Heaven ${ }^{8}$ using the CASPT2-SO approach. Dolg and co-workers ${ }^{19,20}$ performed multireference (MRCI)

[^0]
and relativistic calculations, at the all-electron DKH level and also with pseudopotentials (PP), on the low-lying states of UH with $\mathrm{U} 5 f^{3}$ configurations. Their calculations predicted 16 states below $\sim 0.5 \mathrm{eV}$, also yielding a ${ }^{4} \mathrm{I}_{9 / 2}$ ground state. Andrews and co-workers ${ }^{21,22}$ observed multiple uranium hydrides, $\mathrm{UH}_{x}(x=1-4)$ and $\mathrm{U}_{2} \mathrm{H}_{x}(x=2,4)$, as products of laser-ablated U atoms reacting with gaseous $\mathrm{H}_{2}$ and HF in solid Ar and Ne matrices. For UH , a vibrational band at 1423.6 $\mathrm{cm}^{-1}$ was assigned based on its density functional theory calculations for the quartet ground state. Recently, Armentrout and co-workers have carried out experimental kinetic reactions of an uranium atomic cation $\left(\mathrm{U}^{+}\right)$with $\mathrm{H}_{2}, \mathrm{D}_{2}$, and HD via guided ion beam mass spectrometry determining a bond dissociation energy ( BDE ) of $2.48 \pm 0.06 \mathrm{eV}\left(\mathrm{U}^{+}-\mathrm{H}\right)$ for $\mathrm{UH}^{+},{ }^{23}$ close to the one obtained experimentally for $\mathrm{ThH}^{+}$ $(2.45 \pm 0.07 \mathrm{eV})$ by Cox et al. ${ }^{24}$ Note that the experimental value for the BDE of $\mathrm{ThH}^{+}$does not agree with a high-level calculated value of $2.82 \mathrm{eV} .{ }^{24,25}$ In the same work on $\mathrm{UH},{ }^{23}$ they predicted a ${ }^{5} \Phi\left(\pi^{2} \sigma\right)$ ground state with an excited ${ }^{5} \mathrm{I}$ $(\pi \delta \sigma)$ state lying $0.006 \mathrm{eV}\left(48 \mathrm{~cm}^{-1}\right)$ higher in energy at the $\operatorname{CCSD}(\mathrm{T})$ level of theory and a BDE equal to 2.43 eV at the CCSD (T)/CBS-cc-pw-CVnZDK3 level. After the inclusion of spin-orbit effects, the ${ }^{5}$ I state was assigned as the ground state of $\mathrm{UH}^{+}$. Using the CASPT2-RASSI approach with the relativistic DK2 Hamiltonian, these authors ${ }^{23}$ obtained a spin-orbit correction of $0.779 \mathrm{eV}\left(6283 \mathrm{~cm}^{-1}\right)$. We have previously used the methods described in the current work to obtain the thermodynamic properties of the $\mathrm{ThH}^{0 /-1 /+1}$ diatomic molecules and interpret the PES spectra yielding very accurate results. ${ }^{25}$ In that work, we also showed that the $\mathrm{H} / \mathrm{H}^{-}$ligand can provide insights into the atomic states of the actinide atom.

The goal of the current work is to investigate the electronic structures of UH and $\mathrm{UH}^{-}$molecules using high-level computational electronic structure methods, with the intention of expanding our knowledge of the bonding and energetics of the uranium atom with different ligands in the gas phase. The photoelectron spectrum (PES) of $\mathrm{UH}^{-}$is reported together with $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ and CASPT2 calculations including spin-orbit coupling using the state interacting approach. The energies of the low-lying excited electronic states and their rovibrational constants were calculated, as well as vertical detachment energies (VDE) from the anion, the adiabatic electron affinity (AEA), and the BDEs.

## - EXPERIMENTAL AND COMPUTATIONAL METHODS

Experimental Section. The $\mathrm{UH}^{-}$and $\mathrm{UD}^{-}$anions were produced and analyzed using a house-built anion photoelectron spectrometer, which has been described in detail previously. ${ }^{26}$ The apparatus consists of an ion source, a time-of-flight mass spectrometer, a Nd:YAG photodetachment laser, and a magnetic bottle energy analyzer. The uranium hydride anions were generated in a laser vaporization ion source. A rotating, translating uranium rod was ablated using the second harmonic of a Nd:YAG laser ( $532 \mathrm{~nm}, 2.33 \mathrm{eV}$ ), while 20 PSI of UHP $\mathrm{H}_{2}$ gas expanded over the U rod. After pulsing $\mathrm{H}_{2}$ gas over the rod for a minute, the gas flow was shut off, and the experiments were conducting using no backing gas. In order to generate $\mathrm{UD}^{-}$anions, the experiment was repeated with 15 PSI of $D_{2}$ expanded over the $U$ rod. The backing gas was shut off because only diatomic $\mathrm{UH}^{-} / \mathrm{UD}^{-}$, the focus of the current work, were observed with no backing gas. Larger clusters like
$\mathrm{U}_{x} \mathrm{H}_{y}{ }^{-} / \mathrm{U}_{x} \mathrm{D}_{y}{ }^{-}(x \geq 2)$ were observed when backing gas was present. The resulting anions were then extracted with mass selection before entering the photodetachment region.

Anion photoelectron spectroscopy experiments were conducted by crossing a beam of mass-selected actinide hydride negative ions with a fixed-frequency photon beam and energy analyzing the resultant photodetached electrons. The photodetachment process is governed by the energy conservation relationship $h v=$ EBE + EKE, where $h v$ is the photon energy, EBE is the electron binding (photodetachment transition) energy, and EKE is the electron kinetic energy. The second $(532 \mathrm{~nm}, 2.33 \mathrm{eV})$ harmonic of an Nd:YAG laser was used to photodetach electrons from the $\mathrm{UH}^{-}$and $\mathrm{UD}^{-}$anions. The PESs were calibrated against the known transitions of $\mathrm{Cu}^{-} .{ }^{27}$ The resolution of the magnetic bottle energy analyzer is $\sim 50$ meV at 1 eV EKE.

Computational Methods. Spectroscopic constants including harmonic frequencies $\left(\omega_{\mathrm{e}}\right)$, anharmonic constants ( $\omega_{\mathrm{e}} x_{\mathrm{e}}$ ), and optimized equilibrium bond lengths were obtained for diatomic UH and the anion $\mathrm{UH}^{-}$at the $\operatorname{CCSD}(\mathrm{T})^{28-31}$ level of theory using the MOLPRO program package. ${ }^{32,33}$ The calculations were performed using the third-order Douglas-Kroll-Hess Hamiltonian (DKH3) ${ }^{34-36}$ with the aug-cc-pVnZ basis set for $\mathrm{H}^{37,38}$ and the cc-pwCVnZ-DK3 basis set for $\mathrm{U}^{39}$ (abbreviated as as/awn-DK). The diatomic potential energy curves were obtained by seven single-point calculations distributed around the approximated equilibrium bond length $\left(r-r_{\mathrm{e}}=-0.3,-0.2,-0.1,0.0,+0.1,+0.3,+0.5\right.$ in Bohr). The optimized $\operatorname{CCSD}(\mathrm{T})$ energies were extrapolated to the complete basis set (CBS) limit using a mixed Gaussian/ exponential ${ }^{40}$ for basis sets with $n=\mathrm{D}, \mathrm{T}, \mathrm{Q}$ (awCVnZ-DK)

$$
\begin{equation*}
E(n)=E_{\mathrm{CBS}}+A \exp [-(n-1)]+B \exp \left[-(n-1)^{2}\right] \tag{1}
\end{equation*}
$$

The valence space included the $6 s, 6 p, 6 d, 5 f$, and $7 s$ valence electrons on $U$ and the $1 s$ electron on $H$. Core-valence correlation effects were included by correlating the core-shell $5 \mathrm{~s}, 5 \mathrm{p}$, and 5d electrons. The open-shell calculations were done with the $\mathrm{R} / \mathrm{UCCSD}(\mathrm{T})$ approach, where a restricted openshell Hartree-Fock calculation was performed and the spin constraint was then relaxed in the coupled-cluster calculation. ${ }^{30,41-43}$

In order to better describe the low-lying excited states of $\mathrm{UH} / \mathrm{UH}^{-}$, the complete active space self-consistent field (CASSCF) ${ }^{44,45}$ approach was used to represent each lowest spin-free state, $\Lambda \mathrm{S}$, followed by second-order perturbation theory (CASPT2) ${ }^{46,47}$ calculations and a treatment of spinorbit coupling by the state interacting method. The atomic basis functions used in the expansion of the molecular orbitals were the aug-cc-pVnZ basis set ${ }^{37,48}$ for hydrogen and the ccpV VZ-PP basis sets ${ }^{20,39}$ for uranium, for $n=\mathrm{D}, \mathrm{T}$, and Q . The U basis set includes a small-core energy consistent 60 -electron effective core potential (abbreviated as PP) optimized in a multiconfigurational Dirac-Hartree-Fock calculation. These calculations were carried out in the highest Abelian point group available, $C_{2 v}$, for both molecules. Expectation values of $L_{z}{ }^{2}$ were calculated to ensure that both degenerate components of each $\Lambda$ were correctly accounted for.

The identity of the relevant spin-free states that may contribute to the final relativistic states was determined by the molecular states arising from the coupling between the lowest atomic asymptotes. For UH and $\mathrm{UH}^{-}$, an ionic model was initially adopted in which the $\mathrm{H}^{-}$anion is treated as closed
shell species and $\mathrm{U}^{+}\left({ }^{4} \mathrm{I}_{9 / 2}, 5 f^{3} 7 \mathrm{~s}^{2}\right)$ and $\mathrm{U}^{0}\left({ }^{5} \mathrm{~L}, 5 \mathrm{f}^{3} 6 \mathrm{~d}^{1} 7 \mathrm{~s}^{2}\right)$ determined the resulting electronic states. For $\mathrm{U}^{+} \mathrm{H}^{-}$, the coupling yields quartet ( $S=3 / 2$ ) and sextet $(S=5 / 2)$ lowlying states, and for $\mathrm{U}^{0} \mathrm{H}^{-}$, it corresponds to a manifold of septets $(S=3)$ through singlet $(S=0)$ states. For the latter, singlets and triplets were found to lie very high in energy; thus, only quintets and septets were calculated. Initially, the CASSCF active space for UH comprised five electrons in 12 orbitals ( $4 \times a_{1}, 3 \times b_{1}, 3 \times b_{2}$, and $2 \times a_{2}$ ), similar to the approach used previously by Cao et al. ${ }^{19}$ for this molecule. However, this space failed to describe the states of $\mathrm{UH}^{-}$and the $6 \mathrm{~d}_{z}{ }^{2}$ orbital had to be included. The final active space included five electrons in 13 orbitals $\left(5 \times a_{1}, 3 \times b_{1}, 3 \times b_{2}\right.$, and $2 \times \mathrm{a}_{2}$ ) that had predominantly $\mathrm{U} 5 \mathrm{f}, 6 \mathrm{~d}$, and 7 s character, and the lower-energy $\mathrm{U} 5 \mathrm{~s}, 5 \mathrm{p}, 5 \mathrm{~d}, 6 \mathrm{~s}, 6 \mathrm{p}$, and H 1 s orbitals were constrained to be doubly occupied. In the case of $\mathrm{UH}^{-}$, six electrons in 13 orbitals were included giving a $(6 / 13)$ CASSCF. In order to generate a common set of molecular orbitals, the $\Lambda S$ electronic states were state averaged for both species.

On top of the CASSCF -order wavefunction, second-order multiconfigurational perturbation theory (CASPT2) calculations were carried out using the same active space of the preceding calculation to recover dynamical correlation effects. In this step, multiple states are calculated using a Fock operator constructed from a state-averaged density matrix and the zeroth-order Hamiltonians for all states are constructed from the same operator. The frozen-core definition in the CASPT2 included $5 \mathrm{~s}, 5 \mathrm{p}$, and 5 d orbitals of U . In order to avoid intruder states, an IPEA ${ }^{49}$ shift value of 0.28 was used for all states.

The molecular $\Omega$ states arising from the spin-orbit coupling were calculated by applying the state interacting method, as implemented in MOLPRO (SO-CASPT2). ${ }^{50}$ In this method, the spin-orbit eigenstates are obtained by diagonalizing $\mathrm{H}_{\mathrm{el}}+$ $\mathrm{H}_{\mathrm{SO}}$ in a basis of $\mathrm{H}_{\mathrm{el}}$ eigenstates. The matrix elements of $\mathrm{H}_{\text {SO }}$ were constructed using the spin-orbit operator from the U PP. Here, the spin-orbit matrix elements have been calculated throughout at the CASSCF level of the theory using the same basis set as used for the diagonal terms, and the diagonal terms of $\mathrm{H}_{\mathrm{el}}+\mathrm{H}_{\mathrm{SO}}$ have been replaced with CASPT2 energies. The latter energies for the two components of each molecular state with $\Lambda \neq 0$ were manually averaged when needed to ensure exact degeneracies. After diagonalization of $\mathrm{H}_{\mathrm{el}}+\mathrm{H}_{\mathrm{SO}}$, the values of $\Omega$ for each molecule were assigned by converting from a Cartesian eigenfunction basis to a spherical basis and then adding the projection of the spin angular momentum $S$ on the diatomic axis, $\Sigma$, to $\Lambda$ to obtain $\Omega$. These calculations were performed using the an-PP basis set at the corresponding optimized awn-DK bond distances, for $n=\mathrm{D}, \mathrm{T}, \mathrm{Q}$.

The Feller-Peterson-Dixon (FPD) ${ }^{51-54}$ method was used to predict the EA and BDEs for UH. The contributions included in the BDE calculations are defined as follows

$$
\begin{equation*}
D_{0}=\Delta E_{\mathrm{CBS}}+\Delta E_{\mathrm{CV}}+\Delta E_{\mathrm{SO}}+\Delta E_{\mathrm{ZPE}}+\Delta E_{\text {Gaunt }} \tag{2}
\end{equation*}
$$

where $\Delta E_{\text {CBS }}$ is the $\operatorname{CCSD}(\mathrm{T})$ energy extrapolated to the CBS limit using the awn-DK basis set for $n=\mathrm{D}, \mathrm{T}$, and $\mathrm{Q}, \Delta E_{\mathrm{CV}}$ represents the contribution of the additional correlation due to the valence and outer core electrons, $\Delta E_{\text {SO }}$ accounts for the SO-CASPT2 energy corrections, and $\Delta E_{\text {ZPE }}$ is the zero-point energy calculated to be $0.5 \omega_{\mathrm{e}}-0.25 \omega_{\mathrm{e}} x_{\mathrm{e}}$ with frequencies obtained from fitting the $\operatorname{CCSD}(\mathrm{T}) / \mathrm{awQ}$-DK curve. ${ }^{55}$ Contributions from the Gaunt term ( $\Delta E_{\text {Gaunt }}$ ), which accounts for spin-other-orbit coupling, were obtained by the difference
between the four-component Dirac-Coulomb-Gaunt and spinfree Hamiltonian of Dyall ${ }^{56}$ calculations using fully uncontracted basis sets, cc-pVDZ-DK3 on U and aug-cc-pVDZ on H. These calculations were carried out using the DIRAC program. ${ }^{57}$ For the AEA and IE calculations, higher order correlation effects were calculated using the DKH3 Hamiltonian with the MRCC ${ }^{58,59}$ package connected to MOLPRO, where $\Delta E_{\mathrm{T}}=\operatorname{CCSDT}-\operatorname{CCSD}(\mathrm{T})$ with the aT-DK basis sets ${ }^{60,61}$ and $\Delta E_{\mathrm{Q}}=$ CCSDTQ - CSSDT with the aD-DK basis sets. ${ }^{62}$

A bonding analysis of the UH species was made through the natural population analysis (NPA) results based on the natural bond orbitals (NBOs) ${ }^{63,64}$ using NBO7 ${ }^{65,66}$ and are calculated using the MOLPRO program package at the aD-DK level. All the calculations were performed on Linux clusters at The University of Alabama.

## ■ RESULTS AND DISCUSSION

Photoelectron Spectrum of $\mathrm{UH}^{-}$. The ions $\mathrm{UD}^{-}, \mathrm{UC}^{-}$, $\mathrm{UN}^{-}, \mathrm{UO}^{-}$, and $\mathrm{UC}_{2}{ }^{-}$were observed in the mass spectra presented in Figure 1. The PES spectra are given in Figure 2

Figure 1. Observed mass spectra using 15 psi of $D_{2}$ forming the anions $\mathrm{UD}^{-}, \mathrm{UC}^{-}, \mathrm{UN}^{-}, \mathrm{UO}^{-}$, and $\mathrm{UC}_{2}^{-}$.
with selected EBE values in Table 1. The PES spectra for $\mathrm{UH}^{-}$ and $\mathrm{UD}^{-}$exhibit a complex spectrum with seven major peaks, ranging from 0.45 to 2.16 eV , and multiple weak peaks are present within this interval.

Electronic Structure Calculations of $\mathrm{UH}^{-}$. To better understand the PES spectrum, we performed calculations to predict the energetic ordering of low-lying states of $\mathrm{UH}^{-}$and UH. Table 2 gives the low-lying $\Omega$ states at the CASPT2-SO/ aQ-PP level with their $\Lambda S$ composition. Table 3 provides the spectroscopic constants for selected states of $\mathrm{UH}^{-} . \mathrm{UH}^{-}$has a ${ }^{5} \Lambda_{6}$ ground state with a $5 f^{3} 6 \mathrm{~d}^{1}(\mathrm{f} \delta \mathrm{f} \pi \mathrm{f} \varphi \mathrm{d} \delta)$ electronic configuration with the $\mathrm{f} \varphi$ orbital highly mixed with the $\mathrm{f} \pi$ orbital. The first excited state is predicted to be the ${ }^{5} \mathrm{~K}_{5}$ state ( $\mathrm{f} \sigma \mathrm{f} \delta \mathrm{f} \varphi \mathrm{d} \delta)$ and is higher in energy by $0.054 \mathrm{eV}\left(436 \mathrm{~cm}^{-1}\right)$ at the CASPT2-SO level. At the CCSD (T)/CBS level, these states are almost degenerate with the ${ }^{5} \mathrm{~K}$ state higher in energy by only $54 \mathrm{~cm}^{-1}$. In addition, at the $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ level, the second $\left({ }^{5} \mathrm{I}_{4}\right)$ and third excited $\left({ }^{5} \mathrm{H}_{3}\right)$ states have an inverted order compared to the $\Omega$ representation results. After the inclusion of spin-orbit effects, the ground state of $\mathrm{UH}^{-}$ lowered its energy by $6912 \mathrm{~cm}^{-1}(0.857 \mathrm{eV})$. The equilibrium bond length and harmonic frequency for the ground state were predicted to be $2.144 \AA$ and $1189.2 \mathrm{~cm}^{-1}$ at the $\operatorname{CCSD}(\mathrm{T}) /$

CBS limit obtained by extrapolating the total energies to obtain the potential energy curve at the CBS limit, respectively.

Electronic Structure Calculations of UH. Table 4 gives the low-lying $\Omega$ states at the CASPT2-SO/aQ-PP level with their $\Lambda S$ composition. Table 5 shows the spectroscopic constants for selected states for UH. There are 62 quartet and sextet states within 2.0 eV . The ground state of UH is predicted to be ${ }^{4} \mathrm{I}_{9 / 2}\left(5 f^{3} 7 \mathrm{~s}^{2}\right)$, which has the unpaired f electrons in the $\mathrm{f} \varphi \mathrm{f} \delta \mathrm{f} \pi$ orbitals, in agreement with the ground state of the $\mathrm{U}^{+}$atom $\left({ }^{4} \mathrm{I}_{9 / 2}\right)$. The low-lying states of UH arise from lowering the atomic orbital angular momentum $\left(M_{L}\right)$ of the ${ }^{4} \mathrm{I}\left(\mathrm{U}^{+}\right)$atomic state yielding the observed $\mathrm{H}, \Gamma, \Phi, \Delta, \Pi$, and $\Sigma$ states. The lowest excited state $\left({ }^{4} \mathrm{H}_{7 / 2}\right)$ of UH has the $\mathrm{f} \varphi$ $\mathrm{f} \delta \mathrm{f} \sigma$ electronic configuration and is higher in energy by only $0.014 \mathrm{eV}\left(113 \mathrm{~cm}^{-1}\right)$. Likewise, the second excited state, identified as ${ }^{4} \Gamma_{5 / 2}$, has a lower angular momentum configuration $\mathrm{f} \varphi \mathrm{f} \pi \mathrm{f} \sigma$ and is only $0.027 \mathrm{eV}\left(218 \mathrm{~cm}^{-1}\right)$ higher than the ground state. These are consistent with the expected ordering of the substates of $\mathrm{U}^{+}$. The same energetic order of states is observed at the $\operatorname{CCSD}(\mathrm{T})$ level, but the ${ }^{4} \mathrm{H}_{7 / 2}$ state is

now higher by $0.026 \mathrm{eV}\left(210 \mathrm{~cm}^{-1}\right)$ and the ${ }^{4} \Gamma_{5 / 2}$ state is higher by $0.195 \mathrm{eV}\left(1573 \mathrm{~cm}^{-1}\right)$. The equilibrium bond length and harmonic frequency for the ground state were predicted to be $2.016 \AA$ and $1480.5 \mathrm{~cm}^{-1}$ at the $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ limit, respectively, in agreement with the previous report by Cao et al. ${ }^{19}\left(2.008 \AA, 1501 \mathrm{~cm}^{-1}\right)$ using the MRCI-SO all-electron DKH method for the same electronic state. Note that addition of an electron to UH to form $\mathrm{UH}^{-}$increases the bond distance by $0.13 \AA$ and decreases $\omega_{\mathrm{e}}$ by $280 \mathrm{~cm}^{-1}$.

The lowest-lying sextet state $\left({ }^{6} \Lambda_{11 / 2}\right)$ is located 0.302 eV ( $2436 \mathrm{~cm}^{-1}$ ) above the ground state. The energetic profile of the $\Omega$ states of UH resulting from the $\Lambda \mathrm{S}$ quartet and sextet states is illustrated in Figure 3. Potential energy curves were obtained by a seven-point fit procedure around the optimized $\operatorname{CCSD}(\mathrm{T}) / \mathrm{awQ}$-DK equilibrium distance. ${ }^{55}$ Table 6 contains the calculated rovibrational constants with adiabatic excitation energies $\left(T_{\mathrm{e}}\right)<7000 \mathrm{~cm}^{-1}$. In general, the $r_{\mathrm{e}}$ values are smaller and the frequencies slightly larger than the ones in Table 5. The interaction of several states between 3000 and $3500 \mathrm{~cm}^{-1}$ leads to more anharmonic potential curves as evidenced by the vibrational constants. The $T_{\mathrm{e}}$ values for the five lowest-lying states ( $\Omega=9 / 2,7 / 2,5 / 2,3 / 2,1 / 2$ ) are nearly the same as the vertical energies collected in Table 4, as they originate from quartet states with very similar bond lengths.
The inclusion of spin-orbit effects leads to the ${ }^{4} \mathrm{I}_{9 / 2}$ and ${ }^{4} \mathrm{H}_{7 / 2}$ states being very close energetically at the MR-PT2 level, differing from what was predicted at the $\operatorname{CCSD}(\mathrm{T})$ level.

Similar results were found by Bross and Peterson ${ }^{7}$ at the CASPT2-SO/CBS for UCl, which has a ${ }^{4} \mathrm{H}_{7 / 2}$ state only 0.009 $\mathrm{eV}\left(76 \mathrm{~cm}^{-1}\right)$ above the ground state $\left({ }^{4} \mathrm{I}_{9 / 2}\right)$. Cao et al. ${ }^{19}$ reported vertical excitation energies of 0.039 and 0.056 eV for the ${ }^{4} \mathrm{H}_{7 / 2}$ and ${ }^{4} \Gamma_{5 / 2}$ states, respectively, for UH, slightly higher than the ones predicted in the current work. At the CASPT2-SO/aQ-PP level at the optimized UH ( ${ }^{4}$ I) $\operatorname{CCSD}(\mathrm{T}) /$ awQDK geometry, the spin-orbit correction of the UH ground state $\left({ }^{4} \mathrm{I}_{9 / 2}\right)$ is $5782 \mathrm{~cm}^{-1}$. As shown in Table 4, the ground state is well described by a single $\Lambda$ S state, consisting of $78 \%{ }^{4} \mathrm{I}$ and $18 \%{ }^{4} \mathrm{H}$, whereas the ${ }^{4} \mathrm{H}_{7 / 2}$ and ${ }^{4} \Gamma_{5 / 2}$ states present considerable admixtures from other $\Lambda \mathrm{S}$ states.
The results for UH are very similar to those for UF and $\mathrm{UCl},{ }^{7}$ as UF has a ${ }^{4} \mathrm{I}_{9 / 2}$ ground state composed of the $81 \%{ }^{4} \mathrm{I}+$ $16 \%{ }^{4} \mathrm{H}$ mixture, whereas for UCl , it consists of $77 \%{ }^{4} \mathrm{I}$ and $19 \%{ }^{4} \mathrm{H}$. We note that only a few states are reasonably described by a single $\Lambda \mathrm{S}$, with most excited states being highly mixed.

Electron Detachment Energies. We first discuss the AEA as we will build the computed photodetachment energy ordering from this starting point. The FPD components for the AEA and the ionization energy (IE) are collected in Table 7. The AEAs were obtained by taking the energy differences between the ground states of $\mathrm{UH}^{-}\left({ }^{5} \Lambda_{6}\right)$ and $\mathrm{UH}\left({ }^{4} \mathrm{I}_{9 / 2}\right)$. A value of 0.468 eV was calculated for the AEA of UH, including a contribution of 0.14 eV for spin-orbit effects from the SOCASPT2 calculation, which is added to the $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ value of 0.303 eV . The Gaunt correction is 0.013 eV , and that for higher order correlation corrections is 0.011 eV up through CCSDTQ. The CASPT2-SO/aQ-PP EA is 0.519 eV . An experimental value of 0.462 eV for AEA from the onset is in good agreement with both values. For comparison, ThH has a SO correction of 0.069 eV for the EA , and $\mathrm{EA}(\mathrm{ThH})$ is 0.36

${ }^{a}$ At the UH $\left({ }^{4} \mathrm{I}\right)$ optimized $\operatorname{CCSD}(\mathrm{T}) / \mathrm{awQ}-\mathrm{DK}$ geometry.
eV higher than $\mathrm{EA}(\mathrm{UH}){ }^{25}$ The EA for the uranium atom was determined experimentally ${ }^{5}$ to be $0.31497(9) \mathrm{eV}$, whereas at the $\operatorname{CCSD}(\mathrm{T})$ level plus a full four component spin-orbit coupling correction, a value of 0.232 eV was obtained. ${ }^{6}$ For $\mathrm{EA}(\mathrm{Th})$, there is better agreement between the experiment, $0.607690(60) \mathrm{eV},{ }^{67}$ and the high level calculated values of $0.599,{ }^{62} 0.59,{ }^{68}$ and 0.565 eV . ${ }^{6}$

The VDE from the UH $\left({ }^{4} \mathrm{I}_{9 / 2}\right)$ energy at the $\mathrm{UH}^{-}\left({ }^{5} \Lambda_{6}\right)$ geometry is 0.056 eV greater than the AEA at the $\operatorname{CCSD}(\mathrm{T}) /$ CBS level. Adding 0.056 eV to the best estimate of the AEA including the SO corrections and excluding the contribution of $\Delta E_{\text {ZPE }}$ results in a VDE of 0.506 eV (Tables 7 and 8). The predicted adiabatic and vertical electron affinities are consistent with the peaks shown in the experimental PES spectrum (Figure 2 and Table 1). The first large maximum peak (A) is observed at 0.551 eV for $\mathrm{UH}^{-}$and 0.558 eV for $\mathrm{UD}^{-}$. Five VDEs are predicted in the range of 0.50 to 0.57 eV , consistent with the first experimental peak. In addition, there could be other peaks between the onset and the first peak due to the

first low-lying ${ }^{5} \mathrm{~K}_{5}$ excited electronic state of $\mathrm{UH}^{-}$at 0.053 eV lowering the VDE.

Continuing the assignment of excited states of UH in the PES spectrum, our calculated results show that there are two states between the experimental A and B maxima at 0.75 and 0.80 eV . There are two states near 0.88 eV that can be assigned to the $\mathbf{B}$ experimental peak and an additional five states between 0.89 and 0.94 eV , which could be part of this peak. The intense experimental peak $C$ with an EBE of 1.008 eV $\left(\mathrm{UH}^{-}\right)$is consistent with the calculated ${ }^{6} \mathrm{H}_{5 / 2}$ state. In addition, there are predicted peaks at 1.04, 1.07, and 1.13 eV . There are two ${ }^{6} \Gamma$ states consistent with the experimental EBE D peak of 1.190 eV for $\mathrm{UH}^{-}$. From 1.32 to 1.41 eV , there are 10 predicted states, which can account for the experimental E peak at 1.371 eV . From 1.45 to 1.56 eV , there are three states. The experimental $\mathbf{F}$ peak is at 1.703 eV , and there are five predicted states between 1.68 and 1.75 eV , which can account for this peak. The next assigned experimental peak is the $\mathbf{G}$ peak at 2.158 eV . Between 1.84 and 2.11 eV , there are 16 states and the higher values of these states at 2.09 and 2.1 eV could account for the observed peak at 2.16 eV . There are then an additional eight states between 2.27 and 2.49 eV .

Thermochemistry. The BDE of UH was obtained as follows. Direct calculation of the $\operatorname{BDE}(\mathrm{UH})$ to obtain the heat of formation following the FPD approach is not straightforward as accurate calculations of the U atom are difficult due to its $7 \mathrm{~s}^{2} 6 \mathrm{~d}^{1} 5 \mathrm{f}^{3}$ ground state. Rather than directly calculating the BDE using the U atom, we can calculate the BDE from the ionization potential of UH because $\mathrm{U}^{+}$with a $5 \mathrm{f}^{3} 7 \mathrm{~s}^{2}$ configuration has only open-shell 5f orbitals. This makes the calculations simpler as we do not have to consider coupling to the $6 d$ orbital as would be found in U . The BDE of $\mathrm{UH}^{+}$is available from the experiment and from high-level calculations, which are consistent with each other. ${ }^{23}$ We redid the calculations of the BDE of $\mathrm{UH}^{+}$using the FPD approach

outlined in the current work with the components in Table 9. We note that the SO correction for $\mathrm{UH}^{+}$is $6040 \mathrm{~cm}^{-1}$ and that for $\mathrm{U}^{+}$is $6704 \mathrm{~cm}^{-1}$ obtained at the CASPT2-SO level. The SO value for $\mathrm{U}^{+}$is consistent with a value of $6851 \mathrm{~cm}^{-1}$ obtained from the expression $\sum_{J}(2 J+1) E(J) / \sum_{J}(2 J+1)$ using the ground state values for $E(J)$ for $\mathrm{U}^{+}{ }^{3}$ We obtain a value of $235.5 \mathrm{~kJ} / \mathrm{mol}$ for the $\operatorname{BDE}\left(\mathrm{UH}^{+}\right)$, which can be compared to an experimental value of $239.3 \pm 5.8 \mathrm{~kJ} / \mathrm{mol}$ $(2.48 \pm 0.06 \mathrm{eV})$ and a calculated value of $234.5 \mathrm{~kJ} / \mathrm{mol}$ at the $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS} / \mathrm{cc}-\mathrm{pwCVnZ}-\mathrm{DK} 3$ level. ${ }^{23}$ The calculated IE of UH is 6.12 eV at the FPD level. In combination with the heat of formation of $\mathrm{UH}^{+}$, which can be readily obtained from the experimental IE of $U$, we can obtain the values for UH, $\mathrm{UH}^{+}$, and $\mathrm{UH}^{-}$given in Table 10. For $\mathrm{UH}^{-}, \Delta H_{\mathrm{f}}^{\circ}$ was
obtained using the AEA and the heat of formation of UH. Standard heats of formation at 298 K were calculated using the approach described by Curtiss et al. ${ }^{69}$ using $6.36^{66}$ and $4.23 \mathrm{~kJ} /$ $\mathrm{mol}^{64}$ for the thermal corrections of U and H , respectively.

Another way to obtain the heat of formation of UH is by reaction 3 building on our work

$$
\begin{equation*}
\mathrm{UH}+\mathrm{WF}_{6} \rightarrow \mathrm{UF}_{6}+\mathrm{WH} \tag{3}
\end{equation*}
$$

on $\mathrm{UCl}_{6}{ }^{70}$ We chose reaction 3 as the nominal oxidation states are the same. $\Delta H_{\mathrm{f}}^{\circ}{ }_{0 \mathrm{~K}}$ of $\mathrm{UF}_{6}$ is $-2142.5 \mathrm{~kJ} / \mathrm{mol},{ }^{63}$ obtained from the experimental value reported by Guillaumont et al. ${ }^{71}$ of $-2148.6 \pm 1.9 \mathrm{~kJ} / \mathrm{mol}$ at 298 K with the thermal correction for 0 to 298 K from Wagman et al. ${ }^{72}$ of $6.1 \mathrm{~kJ} / \mathrm{mol}$. The FPD value ${ }^{73}$ for $\Delta H_{\mathrm{f}}{ }^{\circ}{ }_{\mathrm{OK}}\left(\mathrm{WF}_{6}\right)$ is $-1763.1 \mathrm{~kJ} / \mathrm{mol}$; thus, we can

Table 10. Heats of Formation $\left(\Delta H_{f}{ }^{\circ}\right)$ and BDEs $\left(D_{0}\right)$ of $\mathrm{UH}^{0 /-}$ in $\mathrm{kJ} / \mathrm{mol}$

| diatomic | $\Delta H_{\mathrm{f}}{ }^{\circ}(0 \mathrm{~K})^{a}$ | $\Delta H_{\mathrm{f}}{ }^{\circ}(298 \mathrm{~K})^{a}$ | $\mathrm{D}_{0}{ }^{b}$ |
| :---: | :---: | :---: | :---: |
| UH | 523.5 | 521.6 | 225.5 |
| $\mathrm{UH}^{-}$ | 478.4 | 476.5 | $197.9^{c}$ |
| $\mathrm{UH}^{+}$ | 1113.6 | 1111.7 | $235.5^{d}$ |

${ }^{a}$ We estimate an error of $\pm 10 \mathrm{~kJ} / \mathrm{mol}$ of the heats of formation predominantly due to the error bar for the heat of formation of the U atom. ${ }^{b}$ We estimate an error of $\pm 5 \mathrm{~kJ} / \mathrm{mol}$ for the value of $\mathrm{D}_{0}$ predominantly due to potential errors in the spin-orbit calculations. ${ }^{c}$ To $\mathrm{U}+\mathrm{H}^{-} .{ }^{d}$ To $\mathrm{U}^{+}+\mathrm{H}$.
calculate $\Delta H_{\mathrm{f}}{ }^{\circ}(\mathrm{WH})$ using the FPD approach. We calculate the heat of formation of WH with respect to the ${ }^{7} \mathrm{~S}$ atomic state of tungsten and then correct it to the ground state by $35.31 \mathrm{~kJ} / \mathrm{mol}(8.44 \mathrm{kcal} / \mathrm{mol}) .^{3}$ At the FPD level (see the Supporting Information for details of the calculation), the BDE for WH is $266.6 \mathrm{~kJ} / \mathrm{mol}$ giving $\Delta H_{\mathrm{f}}{ }^{\circ}{ }_{\mathrm{OK}}(\mathrm{WH})=800.5 \mathrm{~kJ} / \mathrm{mol}$. The energy of reaction 3 at the $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ level is -81.5 $\mathrm{kJ} / \mathrm{mol}$ at 0 K giving $\Delta H_{\mathrm{f}}{ }^{\circ}{ }_{\mathrm{K}}(\mathrm{UH})=530.6 \mathrm{~kJ} / \mathrm{mol}$, in close agreement with a value of $523.5 \mathrm{~kJ} / \mathrm{mol}$ from the IE + BDE approach described above. We note that it is critical to include the SO corrections for the MH because the value at the CASPT2-SO/aug-cc-pVQZ-PP level for UH is $-69.2 \mathrm{~kJ} / \mathrm{mol}$, whereas for WH , it is only $-3.3 \mathrm{~kJ} / \mathrm{mol}$.

The BDEs (Table 11) for UH and $\mathrm{UH}^{-}$were calculated from the known atomic heat of formation of $\mathrm{U}\left(\Delta H_{\mathrm{f}}{ }^{\circ}(0 \mathrm{~K})=\right.$ $533.0 \pm 8 \mathrm{~kJ} / \mathrm{mol})^{66}$ and the values for $\mathrm{H}\left(\Delta H_{\mathrm{f}}{ }^{\circ}(0 \mathrm{~K})=\right.$ $216.034 \mathrm{~kJ} / \mathrm{mol})$ and $\mathrm{H}^{-}\left(\Delta H_{\mathrm{f}}^{\circ}(0 \mathrm{~K})=143.264 \mathrm{~kJ} / \mathrm{mol}\right)$ from

${ }^{a} \mathrm{D}_{0}{ }^{0}$. Current work unless noted. ThH from ref 25. ${ }^{b}$ Average $\mathrm{M}=\mathrm{O}$ from the oxide. Values for $\mathrm{MoO}_{3}, \mathrm{WO}_{3}, \mathrm{ZrO}_{2}$, and $\mathrm{HfO}_{2}$ from ref 65 at the $\operatorname{CCSD}(\mathrm{T})$-PW91/CBS level, $\mathrm{UO}_{3}$ from ref 66, and $\mathrm{ThO}_{2}$ from ref 72. ${ }^{c}$ Average $\mathrm{M}-\mathrm{F}$ from the fluoride. Values for $\mathrm{MoF}_{6}$ from ref 73, $\mathrm{WF}_{6}$ from ref $68, \mathrm{UF}_{6}$ from ref 66, and $\mathrm{ZrF}_{4}, \mathrm{HfF}_{4}$, and $\mathrm{ThF}_{4}$ from ref 74.
the active thermochemical tables (ATcT). ${ }^{74-76}$ The values for all of the metal hydrides in Table 11 were calculated in this work except for ThH taken from our prior work. ${ }^{25}$ The BDE for UH is $\sim 20 \%$ weaker than the BDE of ThH even though the bond distances are essentially the same. This can partially be explained by the nonbonding $5 f$ electrons in $U$ having a repulsive interaction with the $\mathrm{H}^{-}$, and such an interaction is not present in Th. The BDE for $\mathrm{UH}^{-}$is lower than that for UH, by $30 \mathrm{~kJ} / \mathrm{mol}$, whereas the BDE for $\mathrm{ThH}^{-}$is $7 \mathrm{~kJ} / \mathrm{mol}$ higher than that for ThH . For the $\mathrm{UH}^{-}$and $\mathrm{ThH}^{-}$anions, dissociation leads to $\mathrm{M}+\mathrm{H}^{-}$, not $\mathrm{M}^{-}+\mathrm{H}$, as the EA of H is larger than those of U and $\mathrm{Th} .^{71}$
We can also compare the trends for various bond energies in a column. The BDE for WH is slightly larger than that for MoH , and the UH BDE is the smallest of these three. The trend in BDEs for ZrH (this work) and HfH (this work) is the same as that for MoH and WH , but the $\mathrm{ThH} \mathrm{BDE}^{25}$ falls in between those of ZrH and HfH . We can compare the average MO BDEs from $\mathrm{MO}_{2}$ and $\mathrm{MO}_{3}$ as well. ${ }^{65,66,77}$ The metals in the +IV oxidation state have higher BDEs than those in the +VI oxidation state. For the $+\mathrm{VI} \mathrm{MO}_{3}$, the BDEs increase from Mo to U , but the +IV oxidation-state BDEs decrease from $\mathrm{ZrO}_{2}$ to $\mathrm{HfO}_{2}$ and then substantially increase for $\mathrm{ThO}_{2}$. The average $\mathrm{M}-\mathrm{F}$ BDEs for $\mathrm{MF}_{4}$ and $\mathrm{MF}_{6}$ increase down the column. ${ }^{66,68,78,79}$ The values for $\mathrm{MF}_{4}$ are larger than those for $\mathrm{MF}_{6}$ in part due to smaller steric interactions in the former. Thus, the ordering of the BDEs depends on the ligand and the metal oxidation state.

Electronic Structure Analysis. As expected, an examination of the molecular orbitals of UH and $\mathrm{UH}^{-}$indicates that bonding in these molecules has mostly ionic character. Table 12 shows the NPA charges and population from the natural bond orbital analysis obtained at the AD-DK level for selected low-lying states of UH and $\mathrm{UH}^{-}$. The interaction of $\mathrm{U}^{+}\left({ }^{4} \mathrm{I}_{9 / 2}\right)$ with $\mathrm{H}^{-}$gives rise to the low-lying UH states. The ground state of UH ( ${ }^{4} \mathrm{I}_{9 / 2}$ ) is well described by the $\mathrm{f} \varphi \mathrm{f} \delta \mathrm{f} \pi$ electronic configuration with the highest occupied MO of $\sigma$ symmetry having strongly 5 f character. Bonding character is observed for the second highest MO, which is a mixture of the atomic functions $6 \mathrm{~d}_{0}+7 \mathrm{~s}(\mathrm{U})$ strongly polarized toward the 1 s H . A similar pattern is observed for the ${ }^{4} \mathrm{H}_{7 / 2}(\mathrm{f} \varphi \mathrm{f} \delta \mathrm{f} \sigma)$ state, which is only 0.014 eV higher in energy than the ground state and is expected to contribute to its $\Lambda$ S composition (Table 4).

The natural charge for U in UH is +0.71 , and that for H is clearly highly negative. These results are consistent with the assignment of an ionic configuration $\left(\mathrm{U}^{+0.71} \mathrm{H}^{-0.71}\right)$ for UH . In this case, the U 7 s orbitals remain double occupied with about 1.88 e , and the U 5 f orbitals have three unpaired electrons (3.0 e) in agreement with the $5 f^{3} 7 \mathrm{~s}^{2}$ configuration associated with the $\mathrm{U}^{+}\left({ }^{4} \mathrm{I}_{\mathrm{u}}\right)$ lowest atomic asymptote. There are 0.38 electrons in the U 6 d , and there are 1.68 electrons in the H 1 s orbital. The populations for the ${ }^{4} \mathrm{I}_{9 / 2}$ and ${ }^{4} \mathrm{H}_{7 / 2}$ states of UH are basically the same. As the $\mathrm{U}^{+}\left({ }^{6} \mathrm{~L}_{\mathrm{u}}\right)$ atomic asymptote is higher by only $289 \mathrm{~cm}^{-1}$, we calculated the atomic charges for the first sextet excited state, ${ }^{6} \Lambda_{11 / 2}$. The atomic charges slightly change to $0.677(\mathrm{U})$ and $-0.677(\mathrm{H})$ as compared to the quartet states. The 6 d population increases by almost one electron to 1.32 e , and the 7 s orbital decreases to 0.98 e corresponding to the expected $5 f^{3} 6 \mathrm{~d}^{1} 7 \mathrm{~s}^{1} \mathrm{U}$ configuration.

The bonding in $\mathrm{UH}^{-}$results from the interaction of U $\left(5 f^{3} 6 \mathrm{~d}^{1} 7 \mathrm{~s}^{2}\right)$ with the closed shell $\mathrm{H}^{-}\left(1 \mathrm{~s}^{2}\right)$. The natural charges calculated for U are -0.12 e in $\mathrm{UH}^{-}$, whereas for H , there is a population of -0.88 e , so most of the additional electron goes

onto the U. U gains -0.83 e as compared to the U in UH , and H is 0.16 e more negative in $\mathrm{UH}^{-}$than in UH . In comparison with UH , the additional electron goes into the 6 d orbitals with a population of 1.20 e. The 7 p population remains very small in $\mathrm{UH}^{-}$as in UH .

## - CONCLUSIONS

The UH and $\mathrm{UH}^{-}$molecules were characterized by high-level electronic structure calculations combined with anion photoelectron spectroscopy experiments to study the interaction of U with this simplest ligand. The ground state of UH is predicted to be ${ }^{4} \mathrm{I}_{9 / 2}(\mathrm{f} \varphi \mathrm{f} \delta \mathrm{f} \pi)$ at both the SO-CASPT2 and $\operatorname{CCSD}(T)$ levels with the ${ }^{4} \mathrm{H}_{7 / 2}$ excited state only 0.014 eV higher in energy. For $\mathrm{UH}^{-}$, the ground state is predicted to be ${ }^{5} \Lambda_{6}$ with ( $\mathrm{f} \delta \mathrm{f} \pi \mathrm{f} \varphi \mathrm{d} \delta$ ) and the first excited state ${ }^{5} \mathrm{~K}_{5}$ higher by 0.054 eV at the CASPT2-SO level. At the $\operatorname{CCSD}(\mathrm{T})$ level, the two states are essentially degenerate, which shows the importance of including spin-orbit effects in the assignment of the low-lying states.

At the FPD level, the AEA of UH is calculated to be 0.468 eV , in good agreement with an extrapolated experimental value of 0.462 V . The theoretical value includes a spin-orbit correction of 0.14 eV . At the CASPT2-SO/aQ-PP level, the AEA was calculated to be 0.519 eV . The EA of UH is about 0.17 eV larger than the EA of the U atom, an increase of $\sim 60 \%$. This is similar to the absolute differences in the electron affinities of Th and ThH. The photodetachment spectrum of $\mathrm{UH}^{-}$is complicated by the large number of low-lying excited states in UH, which can be accessed in less than 2.0 eV . This again is similar to the situation for $\mathrm{ThH}^{-}$photodetachment. The vertical EA, obtained at the FPD level, is predicted to be 0.506 eV . The assignments of the excited states of UH up to $\sim 2.5 \mathrm{eV}$ show consistency with the PES spectrum.

Considering dissociation to $\mathrm{U}^{+}+\mathrm{H}$, the IE of UH at the FPD level was computed to be 6.116 eV including a small spin-orbit correction of -0.032 eV . The IE is 0.08 eV lower than the experimental IE of U , which suggests that H has only a moderate influence as a ligand on the IE. At the CASPT2-SO level, the IE is estimated to be 6.040 eV .

The BDE of UH was obtained from the calculated IE and heat of formation of $\mathrm{UH}^{+}$. The BDE of $\mathrm{UH}^{+}$is estimated to be $235.5 \mathrm{~kJ} / \mathrm{mol}$ at the FPD level, including a $-7.94 \mathrm{~kJ} / \mathrm{mol}$ spinorbit correction, and $\Delta H_{\mathrm{f}}^{\circ}(0 \mathrm{~K})=1113.6 \mathrm{~kJ} / \mathrm{mol}$. For UH, we obtained a BDE of $225.5 \mathrm{~kJ} / \mathrm{mol}$ and $\Delta H_{\mathrm{f}}^{\circ}(0 \mathrm{~K})=523.5 \mathrm{~kJ} /$ mol . These values are essentially the same as the ones obtained from reaction 3. For $\mathrm{UH}^{-}$, we calculated a BDE of $197.9 \mathrm{~kJ} /$ mol with $\Delta H_{\mathrm{f}}^{\circ}(0 \mathrm{~K})=478.4 \mathrm{~kJ} / \mathrm{mol}$. Compared with ThH , the UH BDE is lower by $\sim 20 \%$, which can be explained by the presence of the $f^{3}$ nonbonding electrons on the $U$.

The NBO electronic structure analysis is consistent with the $5 f^{3}$ subconfiguration for the bonding of the $\mathrm{UH}^{0 /-1}$ species and supports the presence of significant ionic character. Considering ionic bonding for $\mathrm{UH}\left(\mathrm{U}^{+} \mathrm{H}^{-}\right)$, there are 21 spin-orbit states in $\mathrm{U}^{+}$below 1 eV , which originate from the $5 f^{3} 7 \mathrm{~s}^{2}$, $5 f^{3} 6 d^{1} 7 s^{1}, 5 f^{3} 6 d^{2}$, and $5 f^{4} 7 s^{1}$ atomic configurations. ${ }^{3}$ If we assume only a covalent bond (UH), there are 19 spin-orbit states in the neutral $U$, which are mostly associated with the $5 f^{3} 6 d^{1} 7 s^{2}$ configuration. ${ }^{3}$ Only a few states are derived from $5 f^{3} 6 d^{2} 7 s^{1}$ and $5 f^{4} 7 s^{2}$ up to 1 eV excitation energy.
